

ANTAGONISTS OF NEUROPILIN RECEPTOR FUNCTION AND USE THEREOF

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

The work described herein was supported, in part, by National Institute of Health grants CA37392 and CA45548. The U.S. Government has certain rights to the invention.

5 FIELD OF THE INVENTION

The present invention relates to antagonists of neuropilin receptor function and use thereof in the treatment of cancer, particularly metastatic cancer, and angiogenic diseases.

10 BACKGROUND OF THE INVENTION

Cancer, its development and treatment is a major health concern. The standard treatments available are few and directed to specific types of cancer, and provide no absolute guarantee of success. Most treatments rely on an approach that involves killing off rapidly growing cells in the hope that rapidly growing cancerous cells will succumb, either to the treatment, or at least be sufficiently reduced in numbers to allow the body's system to eliminate the remainder. However most, of these treatments are non-specific to cancer cells and adversely effect non-malignant cells. Many cancers although having some phenotype relationship are quite diverse. Yet, what treatment works most effectively for one cancer may not be the best means for treating another cancer. Consequently, an appreciation of the severity of the condition must be made before beginning many therapies. In order to most effective, these treatments require not only an early detection of the malignancy, but an appreciation of the severity of the malignancy. Currently, it can be difficult to distinguish cells at a molecular level as it relates to effect on treatment. Thus, methods of being able to screen malignant cells and better understand their disease state are desirable.

While different forms of cancer have different properties, one factor which many cancers share is that they can metastasize. Until such time as metastasis occurs, a tumor, although it may be malignant, is confined to one area of the body. This may cause discomfort and/or pain, or even lead to more serious problems including death, but if it can be located, it may be surgically removed and, if done with adequate care, be treatable. However, once metastasis sets in, cancerous cells have invaded the body and while surgical resection may remove the parent tumor, this does not address other tumors. Only chemotherapy, or some particular form of targeting therapy, then stands any chance of success.

- 10 The process of tumor metastasis is a multistage event involving local invasion and destruction of intercellular matrix, intravasation into blood vessels, lymphatics or other channels of transport, survival in the circulation, extravasation out of the vessels in the secondary site and growth in the new location (Fidler, et al., *Adv. Cancer Res.* 28, 149-250 (1978), Liotta, et al., *Cancer Treatment Res.* 40, 223-238 (1988),
15 Nicolson, *Biochim. Biophys. Acta* 948, 175-224 (1988) and Zetter, *N. Eng. J. Med.* 322, 605-612 (1990)). Success in establishing metastatic deposits requires tumor cells to be able to accomplish these steps sequentially. Common to many steps of the metastatic process is a requirement for motility. The enhanced movement of malignant tumor cells is a major contributor to the progression of the disease toward metastasis.
20 Increased cell motility has been associated with enhanced metastatic potential in animal as well as human tumors (Hosaka, et al., *Gann* 69, 273-276 (1978) and Haemmerlin, et al., *Int. J. Cancer* 27, 603-610 (1981)).

Identifying factors that are associated with onset of tumor metastasis is extremely important. In addition, to using such factors for diagnosis and prognosis, those factors are an important site for identifying new compounds that can be used for treatment and as a target for treatment identifying new modes of treatment such as inhibition of metastasis is highly desirable.

Tumor angiogenesis is essential for both primary tumor expansion and metastatic tumor spread, and angiogenesis itself requires ECM degradation (Blood et al., *Biochim. Biophys. Acta* 1032:89-118 (1990)). Thus, malignancy is a systemic disease in which interactions between the neoplastic cells and their environment play a

crucial role during evolution of the pathological process (Fidler, I. J., *Cancer Metastasis Rev.* 5:29-49 (1986)).

There is mounting evidence that VEGF may be a major regulator of angiogenesis (reviewed in Ferrara, et al., *Endocr. Rev.*, 13, 18-32 (1992); Klagsbrun, et al., *Curr. Biol.*, 3, 699-702 (1993); Ferrara, et al., *Biochem. Biophys. Res. Commun.*, 161, 851-858 (1989)). VEGF was initially purified from the conditioned media of folliculostellate cells (Ferrara, et al., *Biochem. Biophys. Res. Commun.*, 161, 851-858 (1989)) and from a variety of tumor cell lines (Myoken, et al., *Proc. Natl. Acad. Sci. USA*, 88:5819-5823 (1991); Plouet, et al., *EMBO. J.*, 8:3801-3806 (1991)). VEGF was found to be identical to vascular permeability factor, a regulator of blood vessel permeability that was purified from the conditioned medium of U937 cells at the same time (Keck, et al., *Science*, 246:1309-1312 (1989)). VEGF is a specific mitogen for endothelial cells (EC) *in vitro* and a potent angiogenic factor *in vivo*. The expression of VEGF is up-regulated in tissue undergoing vascularization during embryogenesis and the female reproductive cycle (Brier, et al., *Development*, 114:521-532 (1992); Shweiki, et al., *J. Clin. Invest.*, 91:2235-2243 (1993)). High levels of VEGF are expressed in various types of tumors, but not in normal tissue, in response to tumor-induced hypoxia (Shweiki, et al., *Nature* 359:843-846 (1992); Dvorak et al., *J. Exp. Med.*, 174:1275-1278 (1991); Plate, et al., *Cancer Res.*, 53:5822-5827; Ikea, et al., *J. Biol. Chem.*, 270:19761-19766 (1986)). Treatment of tumors with monoclonal antibodies directed against VEGF resulted in a dramatic reduction in tumor mass due to the suppression of tumor angiogenesis (Kim, et al., *Nature*, 382:841-844 (1993)). VEGF appears to play a principle role in many pathological states and processes related to neovascularization. Regulation of VEGF expression in affected tissues could therefore be key in treatment or prevention of VEGF induced neovascularization/angiogenesis.

VEGF exists in a number of different isoforms that are produced by alternative splicing from a single gene containing eight exons (Ferrara, et al., *Endocr. Rev.*, 13:18-32 (1992); Tischer, et al., *J. Biol. Chem.*, 266:11947-11954 (1991); Ferrara, et al., *Trends Cardio Med.*, 3:244-250 (1993); Polterak, et al., *J. Biol. Chem.*, 272:7151-7158 (1997)). Human VEGF isoforms consists of monomers of 121, 145, 165, 189,

and 206 amino acids, each capable of making an active homodimer (Polterak et al., *J. Biol. Chem.*, 272:7151-7158 (1997); Houck, et al., *Mol. Endocrinol.*, 8:1806-1814 (1991)). The VEGF₁₂₁ and VEGF₁₆₅ isoforms are the most abundant. VEGF₁₂₁ is the only VEGF isoforms that does not bind to heparin and is totally secreted into the culture medium. VEGF₁₆₅ is functionally different than VEGF₁₂₁ in that it binds to heparin and cell surface heparin sulfate proteoglycans (HSPGs) and is only partially released into the culture medium (Houck, et al., *J. Biol. Chem.*, 247:28031-28037 (1992); Park, et al., *Mol. Biol. Chem.*, 4:1317-1326 (1993)). The remaining isoforms are entirely associated with cell surface and extracellular matrix HSPGs (Houck, et al., *J. Biol. Chem.*, 247:28031-28037 (1992); Park, et al., *Mol. Biol. Chem.*, 4:1317-1326 (1993)).

VEGF receptor tyrosine kinases, KDR/Flk-1 and/or Flt-1, are mostly expressed by EC (Terman, et al., *Biochem. Biophys. Res. Commun.*, 187:1579-1586 (1992); Shibuya, et al., *Oncogene*, 5:519-524 (1990); De Vries, et al., *Science*, 265:989-991 (1992); Gitay-Goran, et al., *J. Biol. Chem.*, 267:6003-6096 (1992); Jakeman, et al., *J. Clin. Invest.*, 89:244-253 (1992)). It appears that VEGF activities such as mitogenicity, chemotaxis, and induction of morphological changes are mediated by KDR/Flk-1 but not Flt-1, even though both receptors undergo phosphorylation upon binding of VEGF (Millauer, et al., *Cell*, 72:835-846 (1993); Waltenberger, et al., *J. Biol. Chem.*, 269:26988-26995 (1994); Seetharam, et al., *Oncogene*, 10:135-147 (1995); Yoshida, et al., *Growth Factors*, 7:131-138 (1996)). Recently, Soker et al., identified a new VEGF receptor which is expressed on EC and various tumor-derived cell lines such as breast cancer-derived MDA-MB-231 (231) cells (Soker, et al., *J. Biol. Chem.*, 271:5761-5767 (1996)). This receptor requires the VEGF isoform to contain the portion encoded by exon 7. For example, although both VEGF₁₂₁ and VEGF₁₆₅R bind to KDR/Flk-1 and Flt-1, only VEGF₁₆₅ binds to the new receptor. Thus, this is an isoform-specific receptor and has been named the VEGF₁₆₅ receptor (VEGF₁₆₅R). It will also bind the 189 and 206 isoforms. VEGF₁₆₅R has a molecular mass of approximately 130 kDa, and it binds VEGF₁₆₅ with a Kd of about 2×10^{-10} M, compared with approximately 5×10^{-12} M for KDR/Flk-1. In structure-function analysis, it was shown directly that VEGF₁₆₅ binds to VEGF₁₆₅R via its exon 7-

encoded domain which is absent in VEGF₁₂₁ (Soker, et al., *J. Biol. Chem.*, 271:5761-5767 (1996)). However, the function of the receptor was unclear.

Identifying the alterations in gene expression which are associated with malignant tumors, including those involved in tumor progression and angiogenesis, is clearly a prerequisite not only for a full understanding of cancer, but also to develop new rational therapies against cancer.

A further problem arises, in that the genes characteristic of cancerous cells are very often host genes being abnormally expressed. It is quite often the case that a particular protein marker for a given cancer while expressed in high levels in connection with that cancer is also expressed elsewhere throughout the body, albeit at reduced levels.

The current treatment of angiogenic diseases is inadequate. Agents which prevent continued angiogenesis, e.g. drugs (TNP-470), monoclonal antibodies, antisense nucleic acids and proteins (angiostatin and endostatin) are currently being tested. See, Battegay, *J. Mol. Med.*, 73, 333-346 (1995); Hanahan et al., *Cell*, 86, 353-364 (1996); Folkman, *N. Engl. J. Med.*, 333, 1757-1763 (1995). Although preliminary results with the antiangiogenic proteins are promising, there is still a need for identifying genes encoding ligands and receptors involved in angiogenesis for the development of new antiangiogenic therapies.

SUMMARY OF THE INVENTION

We have isolated a cDNA encoding the VEGF₁₆₅ R gene (SEQ ID NO: 1) and have deduced the amino acid sequence of the receptor (SEQ ID NO:2) We have discovered that this novel VEGF receptor is structurally unrelated to Flt-1 or KDR/Flk-1 and is expressed not only by endothelial cells but by non-endothelial cells, including surprisingly tumor cells.

In ascertaining the function of the VEGF₁₆₅R we have further discovered that this receptor has been identified as a cell surface mediator of neuronal cell guidance and called neuropilin-1. Kolodkin et al., *Cell* 90:753-762 (1997). We refer to the receptor as VEGF₁₆₅R/NP-1 or NP-1.

In addition to the expression cloning of VEGF₁₆₅R/NP-1 cDNA we isolated another human cDNA clone whose predicted amino acid sequence was 47% homologous to that of VEGF₁₆₅R/NP-1 and over 90% homologous to rat neuropilin-2 (NP-2) which was recently cloned (Kolodkin, et al., *Cell* 90, 753-762 (1997)).

5 Our results indicate that VEGF₁₆₅R/NP-1 and NP-2 are expressed by both endothelial and tumor cells. (Fig. 19) We have shown that endothelial cells expressing both KDR and VEGF₁₆₅R/NP-1 respond with increased chemotaxis towards VEGF₁₆₅, not VEGF₁₂₁, when compared to endothelial cells expressing KDR alone. While not wishing to be bound by theory, we believe that VEGF₁₆₅R/NP-1 functions in
10 endothelial cells to mediate cell motility as a co-receptor for KDR.

We have also shown in the Boyden chamber motility assay that VEGF₁₆₅ stimulates 231 breast carcinoma cell motility in a dose-response manner (Fig 15A). VEGF₁₂₁ had no effect motility of these cells (Fig 15B). Since tumor cells such as, 231 cells, do not express the VEGF receptors, KDR or Flt-1, while not wishing to be
15 bound by theory, we believe that tumor cells are directly responsive to VEGF₁₆₅ via VEGF₁₆₅R/NP-1.

We have also analyzed two variants of Dunning rat prostate carcinoma cells, AT2.1 cells, which are of low motility and low metastatic potential, and AT3.1 cells, which are highly motile, and metastatic. Cross-linking and Northern blot analysis
20 show that AT3.1 cells express abundant VEGF₁₆₅R/NP-1, capable of binding VEGF₁₆₅, while AT2.1 cells don't express VEGF₁₆₅R/NP-1 (Fig 18). Immunostaining of tumor sections confirmed the expression of VEGF₁₆₅R/NP-1 in AT3.1, but not AT2.1 tumors (Fig 17). Additionally, immunostaining showed that in subcutaneous AT3.1 and PC3 tumors, the tumor cells expressing VEGF₁₆₅R/NP-1 were found
25 preferentially at the invading front of the tumor/dermis boundary (Fig 17). Furthermore, stable clones of AT2.1 cells overexpressing VEGF₁₆₅R/NP-1 had enhanced motility in the Boyden chamber assay. These results indicate that neuropilin expression on tumor cells is associated with the motile, metastatic phenotype and angiogenesis, and thus is an important target for antiangiogenic and anticancer
30 therapy.

The present invention relates to antagonists of neuropilin (NP) receptor function that can be use to inhibit metastasis and angiogenesis. Antagonists of invention can block the receptor preventing ligand binding, disrupt receptor function, or inhibit receptor occurrence. Specific antagonists include, for example, compounds that bind to NP-1 or NP-2 and antibodies that specifically binds the receptor at a region that inhibits receptor function. For example, one can add an effective amount of a compound that binds to NP-1 to disrupt receptor fuction and thus inhibit metastasis.

We have surprisingly discovered that members of the semaphorin/collapsins family are not only inhibitors of neuronal guidance but also inhibitors of endothelial and tumor cell motility in cells that express neuropilin. Accordingly, preferred antagonists include members of the semaphorin/collapsins family or fragments thereof that bind NP and have VEGF antagonist activity as determined, for example, by the human umbilical vein endothelial cell (HUVEC) proliferation assay using VEGF₁₆₅ as set forth in Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997). Preferably, the semaphorin/collapsin has at least a 25% reduction in HUVEC proliferation, more preferably a 50% reduction, even more preferably a 75% reduction, most preferably a 95% reduction.

VEGF antagonist activity of the semaphorin/collapsin may also be determined by inhibition of binding of labeled VEGF₁₆₅ to VEGF₁₆₅R as disclosed in Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)) or to PAE/NP cells. Preferably, the portion inhibits binding by at least 25%, more preferably 50%, most preferably 75%.

In accordance with the present invention, neuropilin antagonists, or nucleic acids, e.g., DNA or RNA, encoding such antagonists, are useful as inhibitors of VEGF and NP function and can be used to treat diseases, disorders or conditions associated with VEGF and NP expression. The antagonists can be used alone or in combination with other anti-VEGF strategies including, for example, those that antagonize VEGF directly (e.g. anti-VEGF antibodies, soluble VEGF receptor extracellular domains), or antagonize VEGF receptors (e.g. anti-KDR antibodies, KDR kinase inhibitors, dominant-negative VEGF receptors) (Presta LG, et al., *Cancer Res.* 57: 4593-4599 (1997), Kendall RL, et al., (1996) *Biochem. Biophys. Res. Commun.* 226: 324-328,

Diseases, disorders, or conditions, associated with VEGF, include, but are not limited to retinal neovascularization, hemangiomas, solid tumor growth, leukemia, metastasis, psoriasis, neovascular glaucoma, diabetic retinopathy, rheumatoid arthritis, endometriosis, mucular degeneration, osteoarthritis, and retinopathy of prematurity (ROP).

Other aspects of the invention are disclosed *infra*.

Figure 1 shows purification of VEGF₁₆₅R From 231 Cells.

25

Figures 2A and 2B show isolation of VEGF₁₆₅R cDNA by Expression Cloning. Photomicrographs (dark field illumination) of COS 7 cells binding ¹²⁵I-VEGF₁₆₅. ¹²⁵I-VEGF₁₆₅ was bound to transfected COS 7 cells which were then washed, fixed, and overlaid with photographic emulsion that was developed as described in the example, *infra*.

Figure 2A shows COS 7 cells were transfected with a primary plasmid pool (#55 of the 231 cell library) representing approximately 3×10^3 clones and one COS 7 cell binding ^{125}I -VEGF₁₆₅ in the first round of screening is shown.

Figure 2 shows several COS 7 cells transfected with a single positive cDNA clone (A2) binding ^{125}I -VEGF₁₆₅ after the third round of screening.

Figure 3 shows the Deduced Amino Acid Sequence of Human VEGF₁₆₅R/NP-1 (SEQ ID NO:3). The deduced 923 amino acid sequence of the open reading frame of VEGF₁₆₅R/NP-1, clone A2 (full insert size of 6.5 kb) is shown. The putative signal peptide sequence (amino acids 1-21) and the putative transmembrane region (amino acids 860-883) are in boxes. The amino acid sequence obtained by N-terminal amino acid sequencing (Figure 3, amino acids 22-39) is underlined. The arrow indicates where the signal peptide has been cleaved and removed, based on comparison of the N-terminal sequence of purified VEGF₁₆₅R/NP-1 and the cDNA sequence. The sequence of human VEGF₁₆₅R/NP-1 reported here differs from that reported by He et al. (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997)) in that we find Lys₂₆ rather than Glu₂₆, and Asp₈₅₅ rather than Glu₈₅₅. Lys₂₆ and Asp₈₅₅ are found, however, in mouse and rat VEGF₁₆₅R/NP-1 (Kwakami et al., *J. Neurobiol.* 29, 1-17 (1995); He and Tessier-Lavigne, *Cell* 90, 739-751 (1997)).

differs

Figure 4 shows the Comparison of the Deduced Amino Acid Sequence of Human VEGF₁₆₅R/NP-1 (SEQ ID NO:2) and NP-2 (SEQ ID NO:4). The deduced open reading frame amino acid sequences of VEGF₁₆₅R/NP-1 and NP-2 are aligned using the DNASIS program. Amino acids that are identical in both open reading frames are shaded. The overall homology between the two sequences is 43%.

Figure 5 shows a Northern Blot Analysis of VEGF₁₆₅R/NP-1 Expression in Human EC and Tumor-Derived Cell Lines. Total RNA samples prepared from HUVEC (lane 1) and tumor-derived breast carcinoma, prostate carcinoma and melanoma cell lines as indicated (lanes 2-8) were resolved on a 1% agarose gel and blotted onto a GeneScreen nylon membrane. The membrane was probed with ^{32}P -

labeled VEGF₁₆₅R/NP-1 cDNA and exposed to X-ray film. Equal RNA loading was demonstrated by ethidium bromide staining of the gel prior to blotting. A major species of VEGF₁₆₅R/NP-1 mRNA of approximately 7 kb was detected in several of the cell lines.

5

Figure 6 shows a Northern Blot Analysis of VEGF₁₆₅R/NP-1 and KDR mRNA in Adult Human Tissues. A pre-made Northern blot membrane containing multiple samples of human mRNA (Clontech) was probed with ³²P-labeled VEGF₁₆₅R/NP-1 cDNA (top) as described in Fig 5, and then stripped and reprobed with ³²P-labeled
10 KDR cDNA (bottom).

Figures 7A and 7B show a Scatchard Analysis of VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1. Figure 7A. Increasing amounts of ¹²⁵I-VEGF₁₆₅ (0.1-50 ng/ml) were added to subconfluent cultures of PAE cells transfected with human VEGF₁₆₅R/NP-1
15 cDNA (PAE/NP-1 cells) in 48 well dishes. Non-specific binding was determined by competition with a 200-fold excess of unlabeled VEGF₁₆₅. After binding, the cells were washed, lysed and the cell-associated radioactivity was determined using a γ counter.

Figure 7B. The binding data shown in Figure 7A were analyzed by the method
20 of Scatchard, and a best fit plot was obtained with the LIGAND program (Munson and Rodbard, 1980). PAE/NP-1 cells express approximately 3×10^5 VEGF₁₆₅ binding sites per cell and bind ¹²⁵I-VEGF₁₆₅ with a K_D of 3.2×10^{-10} M.

Figure 8 shows cross-linking of VEGF₁₆₅ and VEGF₁₂₁ to PAE cells
25 Expressing VEGF₁₆₅R/NP-1 and/or KDR. ¹²⁵I-VEGF₁₆₅ (5 ng/ml) (lanes 1-6) or ¹²⁵I-VEGF₁₂₁ (10 ng/ml) (lanes 7-10) were bound to subconfluent cultures of HUVEC (lane 1), PC3 (lane 2), PAE (lanes 3 and 7), a clone of PAE cells transfected with human VEGF₁₆₅R/NP-1 cDNA (PAE/NP-1) (lanes 4 and 8), a clone of PAE cells transfected with KDR (PAE/KDR) (lanes 5 and 9), and a clone of PAE/KDR cells
30 transfected with human VEGF₁₆₅R/NP-1 cDNA (PAE/KDR/NP-1) (lanes 6 and 10).

The binding was carried out in the presence of 1 $\mu\text{g/ml}$ heparin. At the end of a 2 hour incubation, each ^{125}I -VEGF isoform was chemically cross-linked to the cell surface. The cells were lysed and proteins were resolved by 6% SDS-PAGE. The polyacrylamide gel was dried and exposed to X-ray film. Solid arrows denote radiolabeled complexes containing ^{125}I -VEGF and KDR, open arrows denote radiolabeled complexes containing ^{125}I -VEGF and VEGF₁₆₅R/NP-1.

Figure 9 shows cross linking of VEGF₁₆₅ to PAE/KDR Cells Co-expressing VEGF₁₆₅R/NP-1 Transiently. PAE/KDR cells were transfected with pCPhygro or pCPhyg-NP-1 plasmids as described in "Experimental Procedures", and grown for 3 days in 6 cm dishes. ^{125}I -VEGF₁₆₅ (5 ng/ml) was bound and cross linked to parental PAE/KDR cells (lane 1), to PAE/KDR cells transfected with pCPhygro vector control (V) (lane 2), to PAE/KDR cells transfected with pCPhyg- VEGF₁₆₅R/NP-1 plasmids (VEGF₁₆₅R/NP-1) (lane 3), and to HUVEC (lane 4).). The binding was carried out in the presence of 1 $\mu\text{g/ml}$ heparin. The cells were lysed and proteins were resolved by 6% SDS-PAGE as in Figure 8. Solid arrows denote radiolabeled complexes containing ^{125}I -VEGF₁₆₅ and KDR. Open arrows denote radiolabeled complexes containing ^{125}I -VEGF₁₆₅ and VEGF₁₆₅R/NP-1.

Figure 10 shows inhibition of ^{125}I -VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 interferes with its binding to KDR. ^{125}I -VEGF₁₆₅ (5 ng/ml) was bound to subconfluent cultures of PAE transfected with human VEGF₁₆₅R/NP-1 cDNA (PAE/NP-1) (lanes 1 and 2), PAE/KDR cells (lanes 3 and 4), and PAE/KDR cells transfected with human VEGF₁₆₅R/NP-1 cDNA (PAE/KDR/NP-1) (lanes 5 and 16) in 35 mm dishes. The binding was carried out in the presence (lanes 2, 4, and 6) or the absence (lanes 1, 3, and 5) of 25 $\mu\text{g/ml}$ GST-Ex 7+8. Heparin (1 $\mu\text{g/ml}$) was added to each dish. At the end of a 2 hour incubation, ^{125}I -VEGF₁₆₅ was chemically cross-linked to the cell surface. The cells were lysed and proteins were resolved by 6% SDS-PAGE as in Figure 9. Solid arrows denote radiolabeled complexes containing

^{125}I -VEGF₁₆₅ and KDR, open arrows denote radiolabeled complexes containing ^{125}I -VEGF₁₆₅ and VEGF₁₆₅R/NP-1.

Figures 11A-C show a model for VEGF₁₆₅R/NP-1 modulation of VEGF₁₆₅ Binding to KDR. 11A.Cells expressing KDR alone. 11B.Cells co-expressing KDR and VEGF₁₆₅R/NP-1. 11C.Cells co-expressing KDR and VEGF₁₆₅R/NP-1 in the presence of GST- Ex 7+8 fusion protein.

A single KDR receptor or a KDR-VEGF₁₆₅R/NP-1 pair is shown in top portion. An expanded view showing several receptors is shown in the bottom portion. VEGF₁₆₅ binds to KDR via exon 4 and to VEGF₁₆₅R/NP-1 via exon 7 (Keyt et al. *J. Biol. Chem.* 271,5638-5646 (1996b); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). A rectangular VEGF₁₆₅ molecule represents a suboptimal conformation that doesn't bind to KDR efficiently while a rounded VEGF₁₆₅ molecule represents one that fits better into a binding site. In cells expressing KDR alone, VEGF₁₆₅ binds to KDR in a sub-optimal manner. In cells co-expressing KDR and VEGF₁₆₅R/NP-1, the binding efficiency of VEGF₁₆₅ to KDR is enhanced. It may be that the presence of VEGF₁₆₅R/NP-1 increases the concentration of VEGF₁₆₅ on the cell surface, thereby presenting more growth factor to KDR. Alternatively, VEGF₁₆₅R/NP-1 may induce a change in VEGF₁₆₅ conformation that allows better binding to KDR, or both might occur. In the presence of GST-Ex 7+8, VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 is competitively inhibited and its binding to KDR reverts to a sub-optimal manner.

Figure 12 shows the human NP-2 amino acid sequence (SEQ ID NO:4).

Figures 13A and 13B show the human NP-2 DNA sequence (SEQ ID NO:3).

Figures 14A, 14B and 14C show the nucleotide (SEQ ID NO:1) and amino acid sequences (SEQ ID NO:2) of VEGF₁₆₅R/NP-1.

Figures 15A and 15B show VEGF₁₆₅ stimulation of MDA MB 231 cell motility. (Figure 15A) Dose response of VEGF₁₆₅ motility activity. (Figure 15B) Both VEGF₁₆₅ and bFGF stimulate motility but VEGF₁₂₁ does not.

5 Figures 16A, 16B and 16C show motility and neuropilin-1 expression of Dunning rat prostate carcinoma cell lines AT3.1 (high motility, high metastatic potential) and AT2.1 (low motility, low metastatic potential) cells. (Figure 16A) AT3.1 cells are more motile than AT2.1 cells in a Boyden chamber assay. 125I-VEGF₁₆₅ cross-links neuropilin-1 on AT3.1 cells but does not cross-link to AT2.1
10 cells. (Figure 16C) AT3.1 but not AT2.1 cells express neuropilin-1, while both cell types express VEGF.

 Figures 17A, 17B and 17C show immunostaining of (Figure 17A) a PC3
 subcutaneous tumor in a nude mouse, (Figure 17B) an AT3.1 tumor in a rat, (Figure
15 17C) an AT2.1 tumor in rat with anti-neuropilin-1 antibodies. Neuropilin
 immunostaining is preferentially associated with PC3 and AT3.1 tumor cells at the
 tumor/dermis boundary. Some of these cells cluster around blood vessels. AT2.1
 cells do not express neuropilin-1.

20 Figures 18A and 18B show overexpression of neuropilin-1 in AT2.1 cells.
 (Figure 18A) Western blot, (Figure 18B) motility activity. Three AT2.1 clones (lanes
 4,5,6) express higher amounts of neuropilin-1 protein and are more motile compared
 to parental AT2.1 cells or AT2.1 vector (AT2.1/V) controls and approach AT3.1 cell
 neuropilin-1 levels and migration activity.

Human NP-2

Forward (513-532): 5' CCAACCAGAAGATTGTCCTC 3' (SEQ ID NO:9)
Reverse (1181-1162): 5' GTAGGTAGATGAGGCACTGA 3'. (SEQ ID NO:10)

Figure 20 shows the effects of collapsin-1 treatment on PAE cell motility in a Boyden chamber. Collapsin-1 inhibits, by about 65% the basal migration of PAE cells expressing neuropilin-1 but not PAE cells expressing KDR. alone One collapsin unit is about 3 ng/ml.

Figures 21A and 21B show results of the aortic ring assay. Collapsin was added (Fig. 21A) or not added (Fig. 21B) to a segment of rat aortic ring and the migration of endothelial cells out of the rings and their formation of tubes was monitored after a week in organ culture. Migration and tube formation are inhibited by collapsin-1.

DETAILED DESCRIPTION OF THE INVENTION

We have discovered that there are VEGF receptors (VEGFR) and neuropilins such as VEGF₁₆₅R/NP-1 and NP-2 that are associated with metastatic potential of a malignant cell and angiogenesis. As used herein, "neuropilin" includes not only VEGF₁₆₅R/NP-1 and NP-2 but any neuropilin or VEGFR, where the constituents share at least about 85% homology with either of the above VEGF₁₆₅R/NP-1 and NP-2 can be used. More preferably, such constituent shares at least 90% homology. Still more preferably, each constituent shares at least 95% homology.

Homology is measured by means well known in the art. For example % homology can be determined by any standard algorithm used to compare homologies. These include, but are not limited to BLAST 2.0 such as BLAST 2.0.4 and i. 2.0.5 available from the NIH (See www.ncbi.nlm.nih.gov/BLAST/newblast.html) (Altschul, S.F., et al. Nucleic Acids Res. 25: 3389-3402 (1997)) and DNASIS (Hitachi Software Engineering America, Ltd.). These programs should preferably be set to an automatic setting such as the standard default setting for homology comparisons. As explained by the NIH, the scoring of gapped results tends to be more biologically meaningful than ungapped results.

In accordance with the present invention, antagonists of neuropilin receptor function can be used inhibit or prevent the metastasis process and/or angiogenesis. Antagonists of the invention can block the receptors preventing ligand binding, disrupt receptor function, or inhibit receptor occurrence. Specific antagonists include, for example, compounds that bind to NP-1 or NP-2 and antibodies that specifically binds the receptor at a region that inhibits receptor function. For example, one can add an effective amount of a compound that binds to NP-1 to disrupt receptor function and thus inhibit metastasis.

Preferred antagonists include members of the semaphorin/collapsins family.

20 We have surprisingly discovered that members of the semaphorin/collapsins family are not only inhibitors of neuronal guidance but also inhibitors of endothelial and tumor cell motility in cells that express neuropilin. Collapsin-1 is a particularly preferred antagonist. Other members of the semaphorin collapsin family can be selected by screening for neuropilin binding.

Semaphorin/collapsins are a family of 100 kDa glycoproteins (Luo, et al. (1993) *Cell* 75: 217-227 Kolodkin, et al., (1993) *Cell* 75: 1389-1399, Behar, et al., (1996) *Nature* 383: 525-528.) Semaphorins are the mammalian homologue and collapsins are the chick homologue. Semaphorins are expressed primarily in the developing CNS, but are also found in developing bones and heart. The receptors for the semaphorins are neuropilin-1 and neuropilin-2 (He, et al., *Cell* 90, 739-751 (1997), Kolodkin, et al, *Cell* 90, 753-762 (1997)) and there is ligand binding

Semaphorin/collapsins are known in the art and can be isolated from natural sources or produced using recombinant DNA methods. See, for example, U.S. Patent 5,807,826. Additionally, fragments of the semaphorin/collapsins may be used. For example, a 70 amino acid region within the semaphorin domain specifies the biological activities of three collapsin family members (Koppel, et al., *Neuron* 19: 531-537).

15 We have shown that when collapsin-1 was added to cultures of porcine
endothelial cells (PAE) and PAE neuropilin-1 and/or KDR transfectants, ¹²⁵I-
Collapsin was found to bind to PAE cells expressing neuropilin-1 but not to PAE cells
expressing KDR. Furthermore, in a Boyden chamber assay, collapsin-1 inhibited the
basal migration of PAE expressing neuropilin-1, by about 60-70%, but had no effect
20 on parental PAE or PAE expressing KDR alone (Fig. 20). Inhibition was dose-
dependent and half-maximal inhibition occurred with 50 collapsing units/ml (as
measured on DRG, 1 CU = 3 ng/ml). Thus, semaphorin/collapsins inhibit the motility
of non-neuronal cells as long as neuropilin-1 is expressed.

In accordance with yet another aspect of the present invention, there are provided isolated antibodies or antibody fragments which selectively binds the
30 receptor. The antibody fragments include, for example, Fab, Fab', F(ab')₂ or Fv

Antibodies, or their equivalents, or other receptor antagonists may also be used in accordance with the present invention for the treatment or prophylaxis of cancers.

Prophylaxis may be appropriate even at very early stages of the disease, as it is not known what specific event actually triggers metastasis in any given case. Thus, administration of the antagonists which interfere with receptor activity, may be effected as soon as cancer is diagnosed, and treatment continued for as long as is necessary, preferably until the threat of the disease has been removed. Such treatment may also be used prophylactically in individuals at high risk for development of certain cancers, e.g., prostate or breast.

Chimeric and humanized antibodies are also within the scope of the invention. It is expected that chimeric and humanized antibodies would be less immunogenic in a human subject than the corresponding non-chimeric antibody. A variety of approaches for making chimeric antibodies, comprising for example a non-human variable region and a human constant region, have been described. See, for example, Morrison et al., Proc. Natl. Acad. Sci. U.S.A. 81,6851 (1985); Takeda, et al., Nature 314,452(1985), Cabilly et al., U.S. Pat. No. 4,816,567; Boss et al., U.S. Pat. No. 4,816,397; Tanaguchi et al., European Patent Publication EP 171496; European Patent Publication 0173494, United Kingdom Patent GB 2177096B. Additionally, a chimeric antibody can be

DNA encoding human VEGF₁₆₅R/NP-1 or NP-2 and recombinant human VEGF₁₆₅R/NP-1 or NP-2 may be produced according to the methods set forth in the Examples.

5 The receptors are preferably produced by recombinant methods. A wide variety of molecular and biochemical methods are available for generating and expressing the polypeptides of the present invention; see e.g. the procedures disclosed in *Molecular Cloning, A Laboratory Manual* (2nd Ed., Sambrook, Fritsch and Maniatis, Cold Spring Harbor), *Current Protocols in Molecular Biology* (Eds. Aufubel, Brent, Kingston, More, Feidman, Smith and Stuhl, Greene Publ. Assoc.,
10 Wiley-Interscience, NY, N.Y. 1992) or other procedures that are otherwise known in the art. For example, the polypeptides of the invention may be obtained by chemical synthesis, expression in bacteria such as *E. coli* and eukaryotes such as yeast, baculovirus, or mammalian cell-based expression systems, etc., depending on the size, nature and quantity of the polypeptide.

15 The term "isolated" means that the polypeptide is removed from its original environment (e.g., the native VEGF molecule). For example, a naturally-occurring polynucleotides or polypeptides present in a living animal is not isolated, but the same polynucleotides or DNA or polypeptides, separated from some or all of the coexisting materials in the natural system, is isolated. Such polynucleotides could be part of a
20 vector and/or such polynucleotides or polypeptides could be part of a composition, and still be isolated in that such vector or composition is not part of its natural environment.

Where it is desired to express the receptor or a fragment thereof, any suitable system can be used. The general nature of suitable vectors, expression vectors and
25 constructions therefor will be apparent to those skilled in the art.

Suitable expression vectors may be based on phages or plasmids, both of which are generally host-specific, although these can often be engineered for other hosts. Other suitable vectors include cosmids and retroviruses, and any other vehicles, which may or may not be specific for a given system. Control sequences, such as
30 recognition, promoter, operator, inducer, terminator and other sequences essential

5 A DNA fragment encoding the receptor or fragment thereof, may readily be inserted into a suitable vector. Ideally, the receiving vector has suitable restriction sites for ease of insertion, but blunt-end ligation, for example, may also be used, although this may lead to uncertainty over reading frame and direction of insertion. In such an instance, it is a matter of course to test transformants for expression, 1 in 6 of which
10 should have the correct reading frame. Suitable vectors may be selected as a matter of course by those skilled in the art according to the expression system desired.

By transforming a suitable organism or, preferably, eukaryotic cell line, such as HeLa, with the plasmid obtained, selecting the transformant with ampicillin or by other suitable means if required, and adding tryptophan or other suitable promoter-inducer (such as indoleacrylic acid) if necessary, the desired polypeptide or protein may be expressed. The extent of expression may be analyzed by SDS polyacrylamide gel electrophoresis-SDS-PAGE (Lemelli, *Nature* 227:680-685 (1970)).

Suitable methods for growing and transforming cultures etc. are usefully
20 illustrated in, for example, Maniatis (Molecular Cloning, A Laboratory Notebook,
Maniatis et al. (eds.), Cold Spring Harbor Labs, N.Y. (1989)).

Cultures useful for production of polypeptides or proteins may suitably be cultures of any living cells, and may vary from prokaryotic expression systems up to eukaryotic expression systems. One preferred prokaryotic system is that of *E. coli*, owing to its ease of manipulation. However, it is also possible to use a higher system, such as a mammalian cell line, for expression of a eukaryotic protein. Currently preferred cell lines for transient expression are the HeLa and Cos cell lines. Other expression systems include the Chinese Hamster Ovary (CHO) cell line and the baculovirus system.

30 Other expression systems which may be employed include streptomycetes, for example, and yeasts, such as *Saccharomyces* spp., especially *S. cerevisiae*. Any

system may be used as desired, generally depending on what is required by the operator. Suitable systems may also be used to amplify the genetic material, but it is generally convenient to use *E. coli* for this purpose when only proliferation of the DNA is required.

5 The polypeptides and proteins may be isolated from the fermentation or cell culture and purified using any of a variety of conventional methods including: liquid chromatography such as normal or reversed phase, using HPLC, FPLC and the like; affinity chromatography (such as with inorganic ligands or monoclonal antibodies); size exclusion chromatography; immobilized metal chelate chromatography; gel
10 electrophoresis; and the like. One of skill in the art may select the most appropriate isolation and purification techniques without departing from the scope of this invention.

 The present invention also provides binding assays using VEGF₁₆₅R/NP-1 or NP-2 that permit the ready screening for compounds which affect the binding of the
15 receptor and its ligands, e.g., VEGF₁₆₅. These assays can be used to identify compounds that modulate, preferably inhibit metastasis and/or angiogenesis. However, it is also important to know if a compound enhances metastasis so that its use can be avoided. For example, in a direct binding assay the compound of interest can be added before or after the addition of the labeled ligand, e.g., VEGF₁₆₅, and the
20 effect of the compound on binding or cell motility or angiogenesis can be determined by comparing the degree of binding in that situation against a base line standard with that ligand, not in the presence of the compound. The assay can be adapted depending upon precisely what is being tested.

 The preferred technique for identifying molecules which bind to the neuropilin
25 receptor utilizes a receptor attached to a solid phase, such as the well of an assay plate. The binding of the candidate molecules, which are optionally labeled (e.g., radiolabeled), to the immobilized receptor can be measured. Alternatively, competition for binding of a known, labeled receptor ligand, such as I-¹²⁵ VEGF₁₆₅, can be measured. For screening for antagonists, the receptor can be exposed to a
30 receptor ligand, e.g., VEGF₁₆₅, followed by the putative antagonist, or the ligand and antagonist can be added to the receptor simultaneously, and the ability of the

10

30

5 (VEGF₁₆₅R/NP-1) or SEQ ID NO:3 (NP-2). A nucleic acid is designed which has a sequence complementary to a sequence of the coding or untranslated region of the shown nucleic acid. Alternatively, an antisense nucleic acid can be designed based upon sequences of a VEGF₁₆₅R gene, which can be identified by screening a genomic DNA library with an isolated nucleic acid of the invention. For example, the sequence
0 of an important regulatory element can be determined by standard techniques and a sequence which is antisense to the regulatory element can be designed.

The antisense nucleic acids and oligonucleotides of the invention can be constructed using chemical synthesis and enzymatic ligation reactions using procedures known in the art. The antisense nucleic acid or oligonucleotide can be chemically synthesized using naturally occurring nucleotides or variously modified nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the antisense and sense nucleic acids e.g. phosphorothioate derivatives and acridine substituted nucleotides can be used. Alternatively, the antisense nucleic acids and oligonucleotides can be produced biologically using an expression vector into which a nucleic acid has been subcloned in an antisense orientation (i.e. nucleic acid transcribed from the inserted nucleic acid will be of an antisense orientation to a target nucleic acid of interest). The antisense expression vector is introduced into cells in the form of a recombinant plasmid, phagemid or attenuated virus in which antisense nucleic acids are produced under the control of a high efficiency regulatory region, the activity of which can be determined by the cell type into which the vector is introduced. For a discussion of the regulation of gene expression using antisense genes see Weintraub, H. et al., Antisense RNA as a molecular tool for genetic analysis, Reviews - Trends in Genetics, Vol. 1 (1)1986.

The term "pharmaceutically acceptable" refers to compounds and compositions which may be administered to mammals without undue toxicity. Exemplary pharmaceutically acceptable salts include mineral acid salts such as hydrochlorides,

30 thorough discussion of pharmaceutically acceptable excipients is available in
Remington's Pharmaceutical Sciences (Mack Pub. Co.).

hygromycin B and protease inhibitors were purchased from Sigma (St. Louis, MO). ^{125}I -Sodium, ^{32}P -dCTP, and GeneScreen-Plus hybridization transfer membrane were purchased from DuPont NEN (Boston, MA). Disuccinimidyl suberate (DSS) and IODO-BEADS were purchased from Pierce Chemical Co. (Rockford, IL). Con A

5 Sepharose was purchased from Pharmacia LKB Biotechnology Inc. (Piscataway, NJ). RNazol-B was purchased from TEL-TEST Inc. (Friendswood, TX). Silver Stain kit and Trans-Blot PVDF membranes were purchased from Bio-Rad Laboratories (Hercules, CA). Multiple tissue northern blot membranes were purchased from Clontech (Palo Alto, CA). PolyAtract mRNA isolation kits were purchased from

10 Promega (Madison, WI). RediPrime DNA labeling kits and molecular weight markers were purchased from Amersham (Arlington Heights, IL). Plasmids: pcDNA3.1 was purchased from Invitrogen (Carlsbad, CA), and pCPhygro, containing the CMV promoter and encoding hygromycin B phosphorase, was kindly provided by Dr. Urban Deutsch (Max Plank Institute, Bad Nauheim, Germany). Restriction

15 endonucleases and Ligase were purchased from New England Biolabs, Inc (Beverly, MA). NT-B2 photographic emulsion and x-ray film were purchased from the Eastman Kodak company (Rochester NY).

Cell culture

20 Human umbilical vein EC (HUVEC) were obtained from American Type Culture Collection (ATCC) (Rockville, MD), and grown on gelatin coated dishes in M-199 medium containing 20% fetal calf serum (FCS) and a mixture of glutamine, penicillin and streptomycin (GPS). Basic FGF (2 ng/ml) was added to the culture medium every other day. Parental porcine aortic endothelial (PAE) cells and PAE cells

25 expressing KDR (PAE/KDR) (Waltenberger et al., *J. Biol. Chem.* 269, 26988-26995 (1994)) were kindly provided by Dr. Lena Claesson-Welsh and were grown in F12 medium containing 10% FCS and GPS. MDA-MB-231 cells and MDA-MB-453 cells were obtained from ATCC, and grown in DMEM containing 10% FCS and GPS. The human melanoma cell lines, RU-mel, EP-mel and WK-mel were kindly provided by

30 Dr. Randolph Byer (Boston University Medical School, Boston, MA), and grown in DMEM containing 2% FCS, 8% calf serum and GPS. Human metastatic prostate

adenocarcinoma, LNCaP and prostate carcinoma, PC3 cells were kindly provided by Dr. Michael Freeman (Children's Hospital, Boston, MA), and grown in RPMI 1640 containing 5% FCS and GPS.

5 Purification and protein sequencing

Approximately 5×10^8 MDA-MB-231 cells grown in 150 cm dishes were washed with PBS containing 5 mM EDTA, scraped and centrifuged for 5 min at 500g. The cell pellet was lysed with 150 ml of 20 mM HEPES, pH 8.0, 0.5% triton X-100 and protease inhibitors including 1 mM AEBSF, 5 μ g/ml leupeptin and 5 μ g/ml aprotinin for 30 min on ice, and the lysate was centrifuged at 30,000 x g for 30 min. $MnCl_2$ and $CaCl_2$ were added to the supernatant to obtain a final concentration of 1mM each. The lysate was absorbed onto a Con A Sepharose column (7 ml) and bound proteins were eluted with 15 ml 20 mM HEPES, pH 8.0, 0.2 M NaCl, 0.1% triton X-100 and 1 M methyl- α -D-mannopyranoside at 0.2 ml/min. The elution was repeated twice more at 30 minute intervals. The Con A column eluates were pooled and incubated for 12 h at 4°C with 0.5 ml of VEGF₁₆₅- Sepharose beads, containing about 150 μ g VEGF₁₆₅, prepared as described previously (Wilchek and Miron, *Biochem. Int.* 4, 629-635. (1982)). The VEGF₁₆₅-Sepharose beads were washed with 50 ml of 20 mM HEPES, pH 8.0, 0.2 M NaCl and 0.1% triton X-100 and then with 25 ml of 20 mM HEPES, pH 8.0. The beads were boiled in SDS-PAGE buffer and bound proteins were separated by 6% SDS-PAGE. Proteins were transferred to a TransBlot PVDF membrane using a semi-dry electric blotter (Hoeffer Scientific), and the PVDF membrane was stained with 0.1% Coomassie Brilliant Blue in 40% methanol. The two prominent proteins in a 130-140 kDa doublet were cut out separately and N-terminally sequenced using an Applied Biosystems model 477A microsequenator as a service provided by Dr. William Lane of the Harvard Microchemistry facility (Cambridge, MA).

Expression cloning and DNA sequencing

Complementary DNA (cDNA) was synthesized from 5 μ g 231 mRNA. Double-stranded cDNA was ligated to *EcoRI* adaptors, and size-fractionated on a 5-20% potassium acetate gradient. DNA fragments larger than 2kb were ligated to an eukaryotic expression plasmid, pcDNA3.1. The plasmid library was transfected into

E.coli to yield a primary library of approximately 1×10^7 individual clones. A portion of the transformed bacteria was divided into 240 pools, each representing approximately 3×10^3 individual clones. DNA prepared from each pool was used to transfect COS-7 cells seeded in 12 well dishes, using the Lipofectin reagent according to the manufacturer's instructions. Three days after transfection, the cells were incubated on ice for 2 h with ^{125}I -VEGF₁₆₅ (10 ng/ml) in the presence of 1 $\mu\text{g}/\text{ml}$ heparin, washed and fixed with 4% paraformaldehyde in PBS. ^{125}I -VEGF₁₆₅ binding to individual cells was detected by overlaying the monolayers with photographic emulsion, NT-B2, and developing the emulsion after two days as described (Gearing et al., 1989). Seven positive DNA pools were identified and DNA from one of the positive pools was used to transform E.Coli. The E. coli were sub-divided into 50 separate pools and plated onto 50 LB ampicillin dishes, with each pool representing approximately 100 clones. DNA made from these pools was transfected into COS-7 cells which were screened for ^{125}I -VEGF₁₆₅ binding as described above. Twenty positive pools were detected at this step, and their corresponding DNAs were used to transform *E. Coli*. Each pool was plated onto separate LB ampicillin dishes and DNA was prepared from 96 individual colonies and screened in a 96-well two dimensional grid for ^{125}I -VEGF₁₆₅ binding to transfected COS-7 cells as described above. Seven single clones were identified as being positive at this step. The seven positive plasmid clones were amplified and their DNA was analyzed by restriction enzyme digestion. Six clones showed an identical digestion pattern of digest and one was different. One clone from each group was submitted for automated DNA sequencing.

Northern Analysis

Total RNA was prepared from cells in culture using RNAzol according to the manufacturer's instructions. Samples of 20 μg RNA were separated on a 1% formaldehyde-agarose gel, and transferred to a GeneScreen-Plus membrane. The membrane was hybridized with a ^{32}P labeled fragment of human VEGF₁₆₅R/NP-1 cDNA, corresponding to nucleotides 63-454 in the ORF, at 63°C for 18 h. The membrane was washed and exposed to an x-ray film for 18 h. A commercially-obtained multiple human adult tissue mRNA blot (Clonotech, 2 $\mu\text{g}/\text{lane}$) was probed

for human NP-1 in a similar manner. The multiple tissue blot was stripped by boiling in the presence of 0.5% SDS and re-probed with a ^{32}P labeled fragment of KDR cDNA corresponding to nucleotides 2841-3251 of the ORF (Terman et al., *Oncogene* 6, 1677-1683 (1991)).

5

Transfection of PAE cells

Parental PAE cells and PAE cells expressing KDR (PAE/KDR) (Waltenberger et al., 1994) were obtained from Dr. Lena Claesson-Welsh. Human NP-1 cDNA was digested with *Xho*I and *Xba*I restriction enzymes and subcloned into the
10 corresponding sites of pCPhygro, to yield pCPhyg-NP-1. PAE and PAE/KDR cells were grown in 6 cm dishes and transfected with 5 μg of pCPhyg-NP-1 using Lipofectamine, according to the manufacturer's instructions. Cells were allowed to grow for an additional 48 h and the medium was replaced with fresh medium containing 200 $\mu\text{g}/\text{ml}$ hygromycin B. After 2 weeks, isolated colonies ($5\text{-}10 \times 10^3$
15 cell/colony) were transferred to separate wells of a 48 well dish and grown in the presence of 200 $\mu\text{g}/\text{ml}$ hygromycin B. Stable PAE cell clones expressing VEGF₁₆₅R/NP-1 (PAE/NP-1) or co-expressing VEGF₁₆₅R/NP-1 and KDR (PAE/KDR/NP-1) were screened for VEGF₁₆₅ receptor expression by binding and cross linking of ^{125}I -VEGF₁₆₅. For transient transfection, PAE/KDR cells were
20 transfected with VEGF₁₆₅R/NP-1 as described above and after three days ^{125}I -VEGF₁₆₅ cross-linking analysis was carried out.

Radio-iodination of VEGF, binding and cross-linking experiments.

The radio-iodination of VEGF₁₆₅ and VEGF₁₂₁ using IODO-BEADS was
25 carried out as previously described (Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)). The specific activity ranged from 40,000-100,000 cpm/ng protein. Binding and cross-linking experiments using ^{125}I -VEGF₁₆₅ and ^{125}I -VEGF₁₂₁ were performed as previously described (Gitay-Goren et al., *J. Biol. Chem.* 267, 6093-6098 (1992); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). VEGF binding was quantitated by
30 measuring the cell-associated radioactivity in a γ -counter (Beckman, Gamma 5500). The counts represent the average of three wells. All experiments were repeated at least

5

Purification of VEGF₁₆₅R

Cross-linking of ¹²⁵I-VEGF₁₆₅ to cell surface receptors of 231 cells results in formation of a 165-175 kDa labeled complex (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). These cells have about 1-2 x 10⁵ VEGF₁₆₅ binding sites/cell. In contrast to VEGF₁₆₅, VEGF₁₂₁ does not bind to the 231 cells and does not form a ligand-receptor complex (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). The relatively high VEGF₁₆₅R number and the lack of any detectable KDR or Flt-1 mRNA in 231 cells (not shown) suggested that these cells would be a useful source for VEGF₁₆₅R purification. Preliminary characterization indicated that VEGF₁₆₅R is a glycoprotein and accordingly, a 231 cell lysate prepared from approximately 5 x 10⁸ cells was absorbed onto a Con A Sepharose column. Bound proteins, eluted from the Con A column, were incubated with VEGF₁₆₅-Sepharose and the VEGF₁₆₅- affinity purified proteins were analyzed by SDS-PAGE and silver staining (Figure 9, lane 2). A prominent doublet with a molecular mass of about 130-135 kDa was detected. This size is consistent with the formation of a 165-175 kDa complex of 40-45 kDa VEGF₁₆₅ bound to receptors approximately 130-135 kDa in size (Figure 9, lane 1). The two bands were excised separately and N-terminal amino acid sequencing was carried out (Figure 1, right). Both the upper and lower bands had similar N-terminal amino acid sequences which showed high degrees of sequence homology to the predicted amino acid sequences in the N-terminal regions of mouse (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995)) and human neuropilin-1 (NP-1) (He and Tessier-Lavigne, *Cell* 90739-751 (1997)).

Expression cloning of VEGF₁₆₅R from 231 cell-derived mRNA

Concomitant with the purification, VEGF₁₆₅R was cloned by expression cloning (Aruffo and Seed, *Proc. Natl. Acad. Sci. USA* 84, 8573-8577 (1987a); Aruffo and Seed, *EMBO J.* 6, 3313-3316 (1987b); Gearing et al., *EMBO J.* 8, 3667-3676 (1989)). For expression cloning, 231 cell mRNA was used to prepare a cDNA library of approximately 10⁷ clones in a eukaryotic expression plasmid. *E. coli* transformed with the plasmid library were divided into pools. The DNA prepared from each pool were transfected into COS-7 cells in separate wells and individual cells were screened

for the ability to bind ^{125}I -VEGF₁₆₅ as detected by autoradiography of monolayers overlaid with photographic emulsion (Fig 2A). After three rounds of subpooling and screening, seven single positive cDNA clones were obtained. Figure 2B shows binding of ^{125}I -VEGF₁₆₅ to COS-7 cells transfected with one of these single positive clones

5 (clone A2).

Restriction enzyme analysis revealed that six of the seven positive single clones had identical restriction digestion patterns but that one clone had a pattern that was different (not shown). Sequencing of one of these similar cDNA clones, clone A2 (Figure 3), showed it to be identical to a sequence derived from a human-expressed
10 sequence tag data bank (dbEST). This sequence also showed a high percentage of homology to the sequence of mouse neuropilin, NP-1 (Kawakami et al., *J. Neurobiol* 29, 1-17 (1995)). After we had cloned human VEGF₁₆₅R, two groups reported the cloning of rat and human receptors for semaphorin III and identified them to be NP-1 (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kolodkin et al., *Cell* 90, 753-762
15 (1997)). The 231 cell-derived VEGF₁₆₅R cDNA sequence is virtually identical (see figure legend 3 for exceptions) to the human NP-1 sequence (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997)). Significantly, the predicted amino acid sequence obtained by expression cloning (Figure 3) confirmed the identification of VEGF₁₆₅R as NP-1 that was determined by N-terminal sequencing (Figure 1), and we have therefore
20 named this VEGF receptor, VEGF₁₆₅R/NP-1.

The human VEGF₁₆₅R/NP-1 cDNA sequence predicts an open reading frame (ORF) of 923 amino acids with two hydrophobic regions representing putative signal peptide and transmembrane domains (Figure 3). Overall, the sequence predicts ectodomain, transmembrane and cytoplasmic domains consistent with the structure of
25 a cell surface receptor. The N-terminal sequence obtained via protein purification as shown in Figure 1 is downstream of a 21 amino acid putative hydrophobic signal peptide domain, thereby indicating directly where the signal peptide domain is cleaved and removed. The short cytoplasmic tail of 40 amino acids is consistent with results demonstrating that soluble VEGF₁₆₅R/NP-1 released by partial trypsin digestion of
30 231 cells is similar in size to intact VEGF₁₆₅R/NP-1 (not shown).

Sequence analysis of the one clone obtained by expression cloning that had a different restriction enzyme profile predicted an open reading frame of 931 amino acids with about a 47% homology to VEGF₁₆₅R/NP-1 (Figure 4). This human cDNA has a 93% sequence homology with rat neuropilin-2 (NP-2) and is identical to the recently cloned human NP-2 (Chen et al., *Neuron*, 19, 547-559 (1997)).

Expression of VEGF₁₆₅R/NP-1 in adult cell lines and tissues

Reports of NP-1 gene expression have been limited so far to the nervous system of the developing embryo (Takagi et al., *Dev. Biol.* 122, 90-100 (1987); Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995); Takagi et al., *Dev. Biol.* 170, 207-222 (1995)). Cell surface VEGF₁₆₅R/NP-1, however, is associated with non-neuronal adult cell types such as EC and a variety of tumor-derived cells (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). Northern blot analysis was carried out to determine whether cells that crossed-linked ¹²⁵I-VEGF₁₆₅ also synthesized VEGF₁₆₅R/NP-1 mRNA. (Figure 5). VEGF₁₆₅R/NP-1 mRNA levels were highest in 231 and PC3 cells. VEGF₁₆₅R/NP-1 mRNA was detected to a lesser degree in HUVEC, LNCaP, EP-mel and RU-mel cells. There was little if any expression in MDA-MB-453 and WK-mel cells. The VEGF₁₆₅R/NP-1 gene expression patterns were consistent with our previous results showing that HUVEC, 231, PC3, LNCaP, EP-mel and RU-mel cells bind ¹²⁵I-VEGF₁₆₅ to cell surface VEGF₁₆₅R/NP-1 but that MDA-MB-453 and WK-mel cells do not (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)).

VEGF₁₆₅R/NP-1 gene expression was analyzed also by Northern blot in a variety of adult tissues in comparison to KDR gene expression (Figure 6). VEGF₁₆₅R/NP-1 mRNA levels were relatively highly in adult heart and placenta and relatively moderate in lung, liver, skeletal muscle, kidney and pancreas. A relatively low level of VEGF₁₆₅R/NP-1 mRNA was detected in adult brain. Interestingly, previous analysis of NP-1 gene expression in mouse and chicken brain suggested that this gene was expressed primarily during embryonic development and was greatly diminished after birth (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995); Takagi et al., *Dev. Biol.* 170, 207-222 (1995)). The tissue distribution of KDR mRNA was similar to that of VEGF₁₆₅R/NP-1 with the exception that it was not expressed highly in the

heart. These results indicate that VEGF₁₆₅R/NP-1 is expressed widely in adult non-neuronal tissue, including tissues in which angiogenesis occurs such as heart and placenta.

5 Characterization of VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1

In order to characterize the binding properties of VEGF₁₆₅R/NP-1, porcine aortic endothelial (PAE) cells were transfected with the cDNA of VEGF₁₆₅R/NP-1. The PAE cells were chosen for these expression studies because they express neither KDR, Flt-1 (Waltenberger et al., *J. Biol. Chem.* 269, 26988-26995 (1994)) nor VEGF₁₆₅R. Stable cell lines synthesizing VEGF₁₆₅R/NP-1 (PAE/NP-1) were established and ¹²⁵I-VEGF₁₆₅ binding experiments were carried out (Fig 7). ¹²⁵I-VEGF₁₆₅ binding to PAE/NP-1 cells increased in a dose-dependent manner and reached saturation at approximately 30 ng/ml demonstrating that VEGF₁₆₅R/NP-1 is a specific VEGF₁₆₅ receptor (Figure 7A). Scatchard analysis of VEGF₁₆₅ binding revealed a single class of VEGF₁₆₅ binding sites with a K_d of approximately 3.2 x 10⁻¹⁰ M and approximately 3 x 10⁵ ¹²⁵I-VEGF₁₆₅ binding sites per cell (Figure 7B). Similar K_d values were obtained for several independently-generated PAE/NP-1 clones, although the receptor number varied from clone to clone (not shown). The K_d of 3 x 10⁻¹⁰ M for the PAE/NP-1 cell lines is consistent with the 2-2.8 x 10⁻¹⁰ M K_d values obtained for VEGF₁₆₅R/NP-1 expressed naturally by HUVEC and 231 cells (Gitay-Goren et al., *J. Biol. Chem.* 267, 6093-6098 (1992); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). The binding of ¹²⁵I-VEGF₁₆₅ to PAE/NP-1 cells was enhanced by 1 µg/ml heparin (not shown), consistent with previous studies showing that heparin enhances ¹²⁵I-VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 on HUVEC and 231 cells (Gitay-Goren et al., *J. Biol. Chem.* 267, 6093-6098 (1992); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)).

Isoform-specific binding of VEGF to cells expressing VEGF₁₆₅R/NP-1

VEGF₁₆₅, but not VEGF₁₂₁, binds to VEGF₁₆₅R/NP-1 on HUVEC and 231 cells (Gitay-Goren et al., *J. Biol. Chem.* 271, 5519-5523 (1992); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). To ascertain whether cells transfected with

VEGF₁₆₅R/NP-1 had the same binding specificity, PAE/NP-1 cells were incubated with ¹²⁵I-VEGF₁₆₅ or ¹²⁵I-VEGF₁₂₁ followed by cross-linking (Figure 8). ¹²⁵I-VEGF₁₆₅ did not bind to parental PAE cells (Figure 8, lane 3) but did bind to PAE/NP-1 cells via VEGF₁₆₅R/NP-1 (Figure 8, lane 4). The radiolabeled complexes formed with VEGF₁₆₅R/NP-1 were similar in size to those formed in HUVEC (Figure 8, lane 1) and PC3 cells (Figure 8, lane 2). On the other hand, ¹²⁵I-VEGF₁₂₁, did not bind to either parental PAE (Figure 8, lane 7) or to PAE/NP-1 cells (Figure 8, lane 8). These results demonstrate that the VEGF isoform-specific binding that occurs with cells expressing endogenous VEGF₁₆₅R/NP-1 such as HUVEC, 231 and PC3 cells, can be replicated in cells transfected with VEGF₁₆₅R/NP-1 cDNA and support the finding that VEGF₁₆₅R and NP-1 are identical.

Co-expression of VEGF₁₆₅R/NP-1 and KDR modulates VEGF₁₆₅ binding to KDR

To determine whether expression of VEGF₁₆₅R/NP-1 had any effect on VEGF₁₆₅ interactions with KDR, PAE cells that were previously transfected with KDR cDNA to produce stable clones of PAE/KDR cells (Waltenberger et al., *J. Biol. Chem.* 269, 26988-26995 (1994)), were transfected with VEGF₁₆₅R/NP-1 cDNA and stable clones expressing both receptors (PAE/KDR/NP-1) were obtained. These cells bound ¹²⁵I-VEGF₁₆₅ to KDR (Figure 8, lane 6, upper complex) and to VEGF₁₆₅R/NP-1 (Figure 8, lane 6, lower complex) to yield a cross-linking profile similar to HUVEC (Figure 8, lane 1). On the other hand, the PAE/KDR/NP-1 cells bound ¹²⁵I-VEGF₁₂₁ to form a complex only with KDR (Figure 8, lanes 9 and 10), consistent with the inability of VEGF₁₂₁ to bind VEGF₁₆₅R/NP-1.

It appeared that in cells co-expressing KDR and VEGF₁₆₅R/NP-1 (Figure 8, lane 6), the degree of ¹²⁵I-VEGF₁₆₅-KDR 240 kDa complex formation was enhanced compared to the parental PAE/KDR cells (Figure 8, lane 5). These results were reproducible and the degree of ¹²⁵I-VEGF₁₆₅-KDR 240 kDa complex formation in different clones was correlated positively with the levels of VEGF₁₆₅R/NP-1 expressed (not shown). However, it could not be ruled out definitively that these differential KDR binding results were possibly due to clonal selection post-transfection.

Therefore, parental PAE/KDR cells were transfected with VEGF₁₆₅R/NP-1 cDNA and ¹²⁵I-VEGF₁₆₅ was bound and cross-linked to the cells three days later in order to avoid any diversity of KDR expression among individual clones (Figure 9). A labeled 240 kDa complex containing KDR was formed in parental PAE/KDR cells (Fig 9, lane 1) and in PAE/KDR cells transfected with the expression vector (Figure 9, lane 2). However, when ¹²⁵I-VEGF₁₆₅ was cross-linked to PAE/KDR cells transiently expressing VEGF₁₆₅R/NP-1, a more intensely labeled 240 kDa complex, about 4 times greater, was observed (Figure 9, lane 3), compared to parental PAE/KDR cells (Figure 9, lane 1) and PAE/KDR cells transfected with expression vector (Figure 9, lane 2). These results suggest that co-expression of KDR and VEGF₁₆₅R/NP-1 genes in the same cell enhances the ability of VEGF₁₆₅ to bind to KDR.

A GST-VEGF Exon 7+8 fusion protein inhibits VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 and KDR

We have shown that ¹²⁵I-VEGF₁₆₅ binds to VEGF₁₆₅R/NP-1 through its exon 7-encoded domain (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). In addition, a GST fusion protein containing the peptide encoded by VEGF exon 7+8 (GST-Ex 7+8), inhibits completely the binding of ¹²⁵I-VEGF₁₆₅ to VEGF₁₆₅R/NP-1 associated with 231 cells and HUVEC (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996); Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)). When, added to PAE/NP-1 cells, the fusion protein completely inhibited binding to VEGF₁₆₅R/NP-1 (Figure 10, lane 2 compared to lane 1). On the other hand, it did not inhibit ¹²⁵I-VEGF₁₆₅ binding at all to KDR (Figure 10, lane 4 compared to lane 3). Thus, these results demonstrate that GST-Ex 7+8 binds directly to VEGF₁₆₅R/NP-1 but does not bind to KDR. The effects of GST-Ex 7+8 are different, however, in cells co-expressing both VEGF₁₆₅R/NP-1 and KDR (PAE/KDR/NP-1). Consistent with the results in Figures 8 and 9, the degree of ¹²⁵I-VEGF₁₆₅ binding to KDR in PAE/KDR/NP-1 cells (Figure 10, lane 5) was greater than to the parental PAE/KDR cells (Figure 10, lane 3). Interestingly, in PAE/KDR/NP-1 cells, GST-Ex 7+8 inhibited not only ¹²⁵I-VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 completely as expected, but it also inhibited binding to KDR substantially which was unexpected (Figure 10, lane 6 compared to lane 5). In the

presence of GST-Ex 7+8, binding of ^{125}I -VEGF₁₆₅ to KDR in these cells was reduced to the levels seen in parental PAE/KDR cells not expressing VEGF₁₆₅R/NP-1 (Figure 10, lane 6 compared to lanes 3 and 4). Since the fusion protein does not bind directly to KDR, these results suggest that inhibiting the binding of ^{125}I -VEGF₁₆₅ to

- 5 VEGF₁₆₅R/NP-1 directly, inhibits its binding to KDR indirectly. Taken together, the results in Figures 8, 9 and 10 suggest that interactions of VEGF₁₆₅ with VEGF₁₆₅R/NP-1 enhance VEGF interactions with KDR.

Neuropilin-1 is an isoform-specific VEGF₁₆₅ receptor

- 10 Recently, we described a novel 130-135 kDa VEGF cell surface receptor that binds VEGF₁₆₅ but not VEGF₁₂₁ and that we named, accordingly, VEGF₁₆₅R (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). We have now purified VEGF₁₆₅R, expression cloned its cDNA, and shown it to be identical to human neuropilin-1 (NP-1) (He and Tessier-Lavigne, *Cell* 90 739-751 (1997)). The evidence that VEGF₁₆₅R is
- 15 identical to NP-1 and that NP-1 serves as a receptor for VEGF₁₆₅ is as follows: i) purification of VEGF₁₆₅R protein from human MDA-MB-231 (231) cells using VEGF affinity, yielded a 130-140 kDa doublet upon SDS-PAGE and silver stain. N-terminal sequencing of both proteins yielded the same N-terminal sequence of 18 amino acids that demonstrated a high degree of homology to mouse NP-1 (Kawakami et al., *J.*
- 20 *Neurobiol.* 29, 1-17 (1995)); ii) After we purified VEGF₁₆₅R from human 231 cells, the cloning of human NP-1 was reported (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997)) and the N-terminal sequence of human VEGF₁₆₅R was found to be identical to a sequence in the N-terminal region of human NP-1; iii) Expression cloning using a 231 cell cDNA library resulted in isolation of several cDNA clones and their
- 25 sequences were identical to the human NP-1 cDNA sequence (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997)). The combination of purification and expression cloning has the advantage over previous studies where only expression cloning was used (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kolodkin et al., *Cell* 90, 753-762 (1997)), in allowing unambiguous identification of the NP-1 protein N-terminus;
- 30 iv) Northern blot analysis of NP-1 gene expression was consistent with previous ^{125}I -VEGF₁₆₅ cross-linking experiments (Soker et al., *J. Biol. Chem.* 271, 5761-5767

The discovery that NP-1 serves as a receptor for VEGF₁₆₅ was a surprise since NP-1 had previously been shown to be associated solely with the nervous system during embryonic development (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995); Takagi et al., *Dev. Biol.* 170, 207-222 (1995)) and more recently as a receptor for members of the collapsin/semaphorin family (He and Tessier-Lavigne, *Cell* 90739-751 (1997); Kolodkin et al., *Cell* 90, 753-762 (1997)). NP-1 is a 130-140 kDa transmembrane glycoprotein first identified in the developing *Xenopus* optic system (Takagi et al., *Dev. Biol.* 122, 90-100 (1987); Takagi et al., *Neuron* 7, 295-307 (1991)). NP-1 expression in the nervous system is highly regulated spatially and temporally during development and in particular is associated with those

- developmental stages when axons are actively growing to form neuronal connections.(Fujisawa et al., *Dev. Neurosci.* 17, 343-349 (1995); Kawakami et al., *J. Neurobiol* 29, 1-17 (1995); Takagi et al., *Dev. Biol.* 170, 207-222 (1995)). The NP-1 protein is associated with neuronal axons but not the stomata (Kawakami et al., *J. Neurobiol* 29, 1-17 (1995)). Functionally, neuropilin has been shown to promote neurite outgrowth of optic nerve fibers in vitro (Hirata et al., *Neurosci. Res.* 17, 159-169 (1993)) and to promote cell adhesiveness (Tagaki et al., *Dev. Biol.* 170, 207-222 (1995)). Targeted disruption of NP-1 results in severe abnormalities in the trajectory of efferent fibers of the peripheral nervous system (Kitsukawa et al., *Neuron* 19, 995-1005 (1997)). Based on the these studies, it has been suggested that NP-1 is a neuronal cell recognition molecule that plays a role in axon growth and guidance (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995); He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kitsukawa et al., *Neuron* 19, 995-1005 1997; Kolodkin et al., *Cell* 90, 753-762 (1997)).
- Our results are the first to show that VEGF₁₆₅R/NP-1 is also expressed in adult tissues, in contrast to the earlier studies that have shown that NP-1 expression in *Xenopus*, chicken and mouse is limited to the developmental and early post-natal stages (Fujisawa et al., *Dev. Neurosci.* 17, 343-349 (1995); Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995); Takagi et al., *Dev. Biol.* 170, 207-222 (1995)). For example, in mice, NP-1 is expressed in the developing nervous system starting in the dorsal root ganglia at day 9 and ceases at day 15 (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995)). Our Northern blot analysis of human adult tissue demonstrates relatively high levels of VEGF₁₆₅R/NP-1 mRNA transcripts in heart, placenta, lung, liver, skeletal muscle, kidney and pancreas. Interestingly, there is very little relative expression in adult brain, consistent with the mouse nervous system expression studies (Kawakami et al., *J. Neurobiol.* 29, 1-17 (1995)). VEGF₁₆₅R/NP-1 is also expressed in a number of cultured non-neuronal cell lines including EC and a variety of tumor-derived cells. A possible function of VEGF₁₆₅R/NP-1 in these cells is to mediate angiogenesis as will be discussed below.
- In addition, NP-1 has been identified as a receptor for the collapsin/semaphorin family by expression cloning of a cDNA library obtained from

rat E14 spinal cord and dorsal root ganglion (DRG) tissue (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kolodkin et al., *Cell* 90, 753-762 (1997)). The collapsin/semaphorins (collapsin-D-1/Sema III/Sem D) comprise a large family of transmembrane and secreted glycoproteins that function in repulsive growth cone and axon guidance (Kolodkin et al., *Cell* 75, 1389-1399 (1993)). The repulsive effect of sema III for DRG cells was blocked by anti-NP-1 antibodies (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kolodkin et al., *Cell* 90, 753-762 (1997)). The K_d of sema III binding to NP-1, $0.15-3.25 \times 10^{-10}$ M (He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kolodkin et al., *Cell* 90, 753-762 (1997)) is similar to that of VEGF₁₆₅ binding VEGF₁₆₅/NP-1, which is about 3×10^{-10} M. These results indicate that two structurally different ligands with markedly different biological activities, VEGF-induced stimulation of EC migration and proliferation on one hand, and sema III-induced chemorepulsion of neuronal cells, on the other hand, bind to the same receptor and with similar affinity. An interesting question is whether the two ligands bind to the same site on VEGF₁₆₅R/NP-1 or to different sites. VEGF₁₆₅R/NP-1 has five discrete domains in its ectodomain, and it has been suggested that this diversity of protein modules in NP-1 is consistent with the possibility of multiple binding ligands for NP-1 (Takagi et al., *Neuron* 7, 295-307 (1991); Feiner et al., *Neuron* 19 539-545 (1997); He and Tessier-Lavigne, *Cell* 90 739-751 (1997)). Preliminary analysis does not indicate any large degree of sequence homology between sema III and VEGF exon 7, which is responsible for VEGF binding to VEGF₁₆₅R/NP-1 (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). However there may be some 3-dimensional structural similarities between the two ligands. Since both neurons and blood vessels display branching and directional migration, the question also arises as to whether VEGF₁₆₅ displays any neuronal guidance activity and whether sema III has any EC growth factor activity. These possibilities have not been examined yet. However, it may be that VEGF requires two receptors, KDR and NP-1 for optimal EC growth factor activity (Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)) and that sema III requires NP-1 and an as yet undetermined high affinity receptor for optimal chemorepulsive activity (Feiner et al., *Neuron* 19, 539-545 (1997); He and Tessier-Lavigne, *Cell* 90, 739-751 (1997); Kitsukawa et al., *Neuron* 19, 995-1005 (1997)), so

VEGF₁₆₅R/NP-1 modulates the binding of VEGF₁₆₅ to KDR, a high affinity RTK that is an important regulator of angiogenesis as evidenced by KDR knock out experiments in mice (Shalaby et al., *Nature* 376, 62-66 (1995)). The affinity of KDR for VEGF₁₆₅ is about 50 times greater than for VEGF₁₆₅R/NP-1 (Gitay-Goren et al., *J. Biol. Chem.* 287, 6003-6096 (1992); Waltenberger et al., *J. Biol. Chem.* 269, 26988-26995 (1994)). When VEGF₁₆₅R/NP-1 and KDR are co-expressed, the binding of ¹²⁵I-VEGF₁₆₅ to KDR is enhanced by about 4-fold compared to cells expressing KDR alone. The enhanced binding can be demonstrated in stable clones co-expressing VEGF₁₆₅R/NP-1 and KDR (PAE/KDR/NP-1 cells), and also in PAE/KDR cells transfected transiently with VEGF₁₆₅R/NP-1 cDNA where clonal selection does not take place. Conversely, when the binding of ¹²⁵I-VEGF₁₆₅ to VEGF₁₆₅R/NP-1 in PAE/KDR/NP-1 cells is inhibited completely by a GST fusion protein containing VEGF exons 7+8 (GST-Ex 7+8), the binding to KDR is inhibited substantially, down to the levels observed in cells expressing KDR alone. The fusion protein binds to VEGF₁₆₅R/NP-1 directly but is incapable of binding to KDR directly (Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)). Although, not wishing to be bound by theory, we believe that VEGF₁₆₅ binds to VEGF₁₆₅R/NP-1 via the exon 7-encoded domain and facilitates VEGF₁₆₅ binding to KDR via the exon 4-encoded domain (Figure 11). VEGF₁₆₅R/NP-1, with its relatively high receptor/cell number, about 0.2-2 x 10⁵ (Gitay-Goren et al., *J. Biol. Chem.* 287, 6003-6096 (1992); Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)), appears to serve to concentrate VEGF₁₆₅ on the cell surface, thereby providing greater access of VEGF₁₆₅ to KDR. Alternatively, binding to VEGF₁₆₅R/NP-1, VEGF₁₆₅ undergoes a conformational change that enhances its binding to KDR. The end result would be elevated KDR signaling and increased VEGF activity. Although we can demonstrate enhanced binding to KDR, to date we have not been able to demonstrate enhanced VEGF mitogenicity for PAE/KDR/NP-1

cells compared to PAE/KDR cells. One reason is that these cell lines do not proliferate readily in response to VEGF as do HUVEC (Waltenberger et al., *J. Biol. Chem.* 269, 26988-26995 (1994)). Nevertheless, we have shown that VEGF₁₆₅, which binds to both KDR and VEGF₁₆₅R/NP-1, is a better mitogen for HUVEC than is VEGF₁₂₁, which binds only to KDR (Keyt et al., *J. Biol. Chem.* 271, 5638-5646 (1996b); Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)). Furthermore, inhibiting VEGF₁₆₅ binding to VEGF₁₆₅R/NP-1 on HUVEC by GST-EX 7+8, inhibits binding to KDR and also inhibits VEGF₁₆₅-induced HUVEC proliferation, down to the level induced by VEGF₁₂₁ (Soker et al., *J. Biol. Chem.* 272, 31582-31588 (1997)). Taken together, these results suggest a role for VEGF₁₆₅R/NP-1 in mediating VEGF₁₆₅, but not VEGF₁₂₁ mitogenic activity. The concept that dual receptors regulate growth factor binding and activity has been previously demonstrated for TGF- β , bFGF and NGF (Lopez-Casillas et al., *Cell* 67, 785-795 (1991); Yaron et al., *Cell* 64, 841-848 (1991; Barbacid, *Curr. Opin. Cell Biol.* 7, 148-155 (1995)).

Another connection between VEGF₁₆₅R/NP-1 and angiogenesis comes from studies in which NP-1 was overexpressed ectopically in transgenic mice (Kitsuskawa et al., *Develop.* 121, 4309-4318 (1995)). NP-1 overexpression resulted in embryonic lethality and the mice died *in utero* no later than on embryonic day 15.5 and those that survived the best had lower levels of NP-1 expression. Mice overexpressing NP-1 displayed morphologic abnormalities in a limited number of non-neural tissues such as blood vessels, the heart and the limbs. NP-1 was expressed in both the EC and in the mesenchymal cells surrounding the EC. The embryos possessed excess and abnormal capillaries and blood vessels compared to normal counterparts and in some cases dilated blood vessels as well. Some of the chimeric mice showed hemorrhaging, mainly in the head and neck. These results are consistent with the possibility that ectopic overexpression of VEGF₁₆₅R/NP-1 results in inappropriate VEGF₁₆₅ activity, thereby mediating enhanced and/or aberrant angiogenesis. Another piece of evidence for a link between NP-1 and angiogenesis comes from a recent report showing that in mice targeted for disruption of the NP-1 gene, the embryos have severe abnormalities in the peripheral nervous system but that their death *in utero* at days 10.5-12.5 is most

5 The greatest degree of VEGF₁₆₅R/NP-1 expression that we have detected so far occurs in tumor-derived cells such as 231 breast carcinoma cells and PC3 prostate carcinoma cells, far more than occurs in HUVEC. The tumor cells express abundant levels of VEGF₁₆₅R/NP-1 mRNA and about 200,000 VEGF₁₆₅ receptors/cell (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). On the other hand, these tumor cells do not
10 express KDR or Flt-1 so that VEGF₁₆₅R/NP-1 is the only VEGF receptor associated with these cells. The tumor cells are therefore useful for testing whether VEGF₁₆₅R/NP-1 is a functional receptor for VEGF₁₆₅ in the absence of a KDR background. To date, we have not been able to show that VEGF₁₆₅R/NP-1 mediates a VEGF₁₆₅ signal in tumor-derived cells as measured by receptor tyrosine
15 phosphorylation. Nevertheless, VEGF₁₆₅ might have an effect on tumor cells by inducing some, as yet undetermined activity such as enhanced survival, differentiation, or motility. A recent report has demonstrated that glioma cells express a 190 kDa protein that binds VEGF₁₆₅ but not VEGF₁₂₁ efficiently (Omura et al., *J. Biol. Chem.* 272, 23317-23322 (1997)). No stimulation of tyrosine phosphorylation could be
20 demonstrated upon binding of VEGF₁₆₅ to this receptor. Whether the 190 kDa isoform-specific receptor is related to VEGF₁₆₅R/NP-1 is not known presently.

VEGF₁₆₅R/NP-1 may have a storage and sequestration function for VEGF₁₆₅. One might envision that VEGF₁₆₅ is produced by a tumor cell and binds to VEGF₁₆₅R/NP-1 on that cell via the exon 7-encoded domain (Soker et al., *J. Biol. Chem.* 271, 5761-5767 (1996)). The stored VEGF₁₆₅ could be then released to stimulate tumor angiogenesis in a paracrine manner. Alternatively, VEGF₁₆₅R/NP-1 may mediate a juxtacrine effect in which VEGF₁₆₅ is bound to VEGF₁₆₅R/NP-1 on a tumor cell via the exon 7-encoded domain and is also bound to KDR on a neighboring EC via the exon 4-encoded domain (Keyt et al., *J. Biol. Chem.* 271, 5638-5646 (1996b)). Such a mechanism could result in a more efficient way for tumor cells to attract EC, thereby enhancing tumor angiogenesis.

In summary, we have demonstrated by independent purification and expression cloning methods that the VEGF isoform specific receptor, VEGF₁₆₅R, is identical to NP-1, a cell surface protein previously identified as playing a role in embryonic development of the nervous system and as being a receptor for the
5 collapsins/semaphorins. Furthermore, binding to VEGF₁₆₅R/NP-1 enhances the binding of VEGF₁₆₅ to KDR on EC and tumor cells.

Experimental Rationale

We have discovered that tumor cell neuropilin-1 mediates tumor cell motility
10 and thereby metastasis. In a Boyden chamber motility assay, VEGF₁₆₅ (50 ng/ml) stimulates 231 breast carcinoma cell motility in a dose-response manner, with a maximal 2-fold stimulation (Fig. 15A). On the other hand, VEGF₁₂₁ has no effect on motility of these cells (Fig. 15B). Since 231 cells do not express KDR or Flt-1, these results suggest that tumor cells are directly responsive to VEGF₁₆₅ and that VEGF₁₆₅
15 might signal tumor cells via neuropilin-1. Possible candidates for mediating VEGF₁₆₅-induced motility of carcinoma cells are PI3-kinase (PI3-K) (Carpenter, et al. (1996) *Curr. Opin. Cell Biol.* 8: 153-158.). Since 231 cells do not express KDR or Flt-1, these results suggest that tumor cells are directly responsive to VEGF₁₆₅ and that VEGF₁₆₅ might signal tumor cells via neuropilin-1.

20 The other type of evidence is that neuropilin-1 expression might be associated with tumor cell motility. We have analyzed two variants of Dunning rat prostate carcinoma cells, AT2.1 cells, which are of low motility and low metastatic potential, and AT3.1 cells, which are highly motile, and metastatic. Cross-linking and Northern blot analysis show that AT3.1 cells express abundant neuropilin-1, capable of binding
25 VEGF₁₆₅, while AT2.1 cells don't express neuropilin-1 (Fig. 16). Immunostaining of tumor sections confirms the expression of neuropilin-1 in AT3.1, but not AT2.1 tumors (Fig. 17). Furthermore, the immunostaining shows that in subcutaneous AT3.1 and PC3 tumors, the tumor cells expressing neuropilin-1 are found preferentially at the invading front of the tumor/dermis boundary (Fig. 17). To determine more directly
30 whether neuropilin-1 expression is correlated with enhanced motility, neuropilin-1 was overexpressed in AT2.1 cells (Fig. 18). Three stable clones of AT2.1 cells overexpressing neuropilin-1 had enhanced motility in the Boyden chamber assay.

These results indicate that expression of neuropilin-1 in AT2.1 cells enhances their motility. Taken together, it appears that neuropilin-1 expression on tumor cells is associated with the motile, metastatic phenotype.

5 EXAMPLE 2

Experimental Procedures

1. Collapsin/semaphorins. Expression plasmids for expressing and purifying His-tagged collapsin-1 from transfected 293T cells can be produced according to the
10 methods of (Koppel, et al. (1998) *J. Biol. Chem.* 273: 15708-15713, Feiner, et al. (1997) *Neuron* 19: 539-545.). Expression vectors for expressing sema E and sema IV alkaline phosphate (AP) conjugates in cells are disclosed in (He Z, Tessier-Lavigne M. (1997). Neuropilin is a receptor for the axonal chemorepellent semaphorin III. *Cell* 90: 739-751.). Migration was measured in a Boyden chamber Falk, et al., *J. Immunol.*
15 118:239-247 (1980) with increasing concentration of recombinant chick collapsin-1 in the bottom well and PAE cell transfectants in the upper well.
2. Aortic Ring Assay. 200 gram rats were sacrificed and the aorta is dissected between the aortic arch and kidney artery and the adipofibrotic tissue around the aorta
20 was removed. Aortic rings were sliced at 1 mm intervals and embedded in type I collagen gels. Each ring was cultured in one well of a 48-well plate with serum-free endothelial cell medium (GIBCO). The number of microvessels were counted in each ring using a phase microscope (Miao, et al. (1997). *J. Clin. Invest.* 99: 1565-1575.).

We established several endothelial cell lines by transfection of parental porcine aortic endothelial cells (PAE), which normally do not express VEGF receptors (Soker, et al.(1998)*Cell* 92: 735-745). The cell lines included PAE cells expressing neuropilin-1 alone (PAE/NP1), PAE cells expressing KDR alone (PAE/KDR) and
5 PAE cells expressing both neuropilin-1 and KDR (PAE/NP1/KDR). Collapsin-1 was obtained from Dr. Jon Raper, University of Pennsylvania (Luo,et al.(1993)*Cell* 75: 217-227.).

Binding studies demonstrated that ¹²⁵I-collapsin-1 could bind to PAE/NP1 cells and PAE/NP1/KDR cells but not at all to PAE or PAE/KDR cells.

10 In a Boyden chamber assay, collapsin-1 at 50-100 collapsin units/ml (CU) inhibited the basal migration of PAE/NP and PAE/NP1/KDR cells by 70% but had no inhibitory effect, whatsoever, on basal PAE or PAE/KDR cell migration (Fig. 20). This effect is fairly potent since 1 CU represents about 3 ng/ml protein. The collapsin-1 inhibitory effect was inhibited by anti-neuropilin-1 antibodies. These results indicate
15 that collapsins can inhibit the migration of non-neuronal endothelial cells as long as they express neuropilin-1.

Collapsin-1 inhibited the migration of PAE/NP and PAE/NP/KDR cells in the presence of VEGF₁₆₅, to the same degree, the baseline being higher. We have also found that addition of collapsin in a rat aortic ring assay (a model for angiogenesis *in*
20 *vitro*) inhibits the migration of endothelial cells out of the ring, and endothelial tube formation (Fig. 21).
